## MOTION: Position, velocity and acceleration Second Partial Project

In this project we are going to be analyzing position, velocity and acceleration by using the derivatives of their equations to get those values. The main purpose of this project is for us to apply the concepts and knowledge we learned and acquired in class in order to understand them better and know how to use them in real life examples like this one. To solve this problems we'll make use of a software called "Graphmatica" in order to get the graphs and its equations in an easier and faster way. Also, we will apply several rules in order to derive the equations and get the new equations for both velocity and acceleration.

## Conclusions:

## Paola Salazar

As shown in the different graphs and functions in order for us to get the result of the derivative the main procedure used was power rule since not one of the functions include a parenthesis and all of the original functions had an $x$ elevated to a certain power. Because of the great availability of the program used (graphmatica) and the fact that it is free is great for people to use it in order to visually see real life problems.

## Ana Cris Lozano

As a conclusion, I think that this project was very helpful for us to understand better how to apply derivatives in order to find velocity and acceleration given the equation of position. This made us realize how there is math in an everyday situation and we didn't even know. Also, using Graphmatica was very useful because with this software we could accomplish the project in an easier and faster way.

## Caro Salazar

To conclude with this project, it was interesting to apply the class material to it. We can observe that in all our resulting graphs we needed to use power rule to get the derivatives, thanks to graphmatica we were able to solve all of these equations to turn them into graphs and it was really simple and useful to use.
